

*Chemical Effects of light.*2^d. *Thomas Harris**Sept. 1809*

My dear friend

I have just received your letter of the 10th inst. and am
glad to hear from you. I am well and hope these few lines
will find you the same. I have not much news to write at
present. I am still in the same place and doing the same
work. I have not much time to spare for writing at present.

Compelled by the laws and customs of the University of Pennsylvania, to offer something as a preliminary to an examination for a degree in medicine, I have presumed to offer this essay, not as a production worthy that honor, but as a weak attempt towards the attainment of it. In this essay, I shall offer some remarks on the chemical effects of light; and for greater convenience, I shall deliver my observations under the three following Heads.

In the first place, consider the action of light on bodies chemically united. Secondly,

Make some inquiries into the combination of light, And lastly, Infer from analogy its relation to other chemical agents.

On the nature of this peculiar substance, there are two theories, each of which has its advocates, among the learned of Europe and America. Innumerable experiments have been made, and the most ingenious reasoning advanced, in support of each, with the effect perhaps, of establishing more firmly, each theory in the minds of its respective adherents. It is foreign to this essay to enter into the consideration of either, I shall therefore regard this observation only, that I consider each of them ingenious, & each plausible - the theory of Newton to possess the weight of experiment, while that of Huygens is established on the most certain foundation of theory.

We are indebted to Schult, Linnichow, Wollaston & Ritter, for knowledge of some very interesting facts, relative to the chemical rays of light. These are found to occupy, in great abundance, that part of the spectrum, which possesses the heating power in the least degree - the chemical effect decreasing as you approach the red ray - while the heating power is to be found stronger in the red, decreasing as you approach the violet ray. Mr. Ritter and P. Wollaston, from direct experiment, have carried the analogy farther, as the heating power of the solar rays is greatest beyond the red, so the chemical effect is greater beyond the violet ray. Mr. Ritter has come to the conclusion, from the result of his experiments, that there are two species of invisible rays, - one caloric, & which promotes oxidation - the other species capable of separating oxygen, when it is combined, & of counteracting its combination. It has been affirmed, says Professor Murray, that this gentleman, by transmitting the coloured rays through different prisms, has separated them from the chemical rays, and produced a coloured spectrum totally devoid of chemical action.

Light exerts an effect truly chemical, on many organic and inorganic substances. If fresh vegetables are placed in water, and exposed to the action of the dark rays, oxygen gas will be evolved in considerable quantity,

by the decomposition of the water. Dr. Wollhouse in a
note to his edition of Mr. Chevreul's Chemistry, brings forward
another proof of the chemical agency of light, by asserting
that there is a quantity of carbonic acid gas in the wa-
ter, & that it is this which is decomposed by the superior af-
finity of the agent - Dr. Priestley made a number of ex-
periments on atmospheric air, impregnated with gases ne-
cessary to animal life, & from the result of them it appears
that the air was uniformly restored to its primitive purity,
by being exposed to the action of light, when in contact
with fresh vegetables. Mr. Lavoisier advances an op-
inion founded on experiment, tending to prove the
chemical action of light, that the addition of an acid
increases the quantity of oxygen gas which is disengaged,
provided the water is not too much acidulated.

The affinity of oxygen for carbon is known by all phi-
sical chemists to be very great, so great that oxygen at
one time stood first in the tables of chemical affinity for
its attraction for carbon, to produce a decomposition,
argues the necessity of a powerful agent, or a substance
possessing a stronger attraction for one of the principles,
than they do for each other - The carbonic is not
the only instance, among the class of bodies termed the
acids, which attests the identity of light as a chemi-
cal agent, by parting with considerable quantities

of its oxygen, under its influence.

The experimental evidence seems to give up a direct proportion of their oxygen, in answer to the influence of the solar rays — we here have a most decisive proof that it is the agency of light alone, and not heat, which effects the decomposition; for these acids may be converted into the gaseous state very readily, by the application of heat and without decomposition provided the rays of light be excluded. It may be observed however that the chemical action is prevented altogether if a substance be introduced capable of intercepting and absorbing the rays of light; if the bottle be full, and closed with a glass stopper there is no change effected — the mechanical pressure of mercury is sufficient to counteract the decomposing power of the light. These altho' apparently depreciations of the power of the agent, in promoting chemical decomposition, are by no means conclusive against, on the contrary, proving that light is influenced by specific and determinate laws, with other chemical agents.

The great variety of metallic oxides, and the combinations of these oxides with acids which acknowledge the de-oxidizing power of light, is no small evidence of its chemical agency. The red oxide of mercury if exposed to the rays of the sun will lose a portion of its

oxygen and a change of colour will be produced.
It has been observed, by the celebrated Lavoisier, when
he poured of the process for obtaining oxygen gas from
this salt by heat that as the oxygen gas now appears
the nitrous becomes red & seems to prove the prin-
ciple established by M. Berthollet that an obscure heat
can never form oxygen gas and that light is one of
its constituent elements. The muriate of gold & nitrate
of silver have been proved to be capable
of total decomposition, by the action of light, from the
experiments of Scheele, Berthollet, & Mr. Fulham, the
ingenious author of an essay on combustion.

These experiments prove that light not only separates
the principle of various compounds of their oxygen, but
also of their acid - In some of the experiments just
alluded to, of Mr. Scheele & Mr. Fulham, the decomposition
of the muriate of gold, & nitrate of silver was so com-
plete that the metals were obtained completely re-
quired. The influence of light on the organized pro-
ductions of nature, is very remarkable. "Organization,
sensation, spontaneous motion, and all the operations
of life, says Lavoisier, exist only at the surface of the
earth, and in places exposed to the influence of light, and

[Faint, illegible handwriting on lined paper, likely bleed-through from the reverse side.]

[Faint, illegible handwriting on the right edge of the page, possibly from an adjacent page.]

without it nature itself would be lifeless & inanimate. Vegetables when deprived of light, become insipid, inodorous, brittle, and lose that agreeable variety of shade, which is so eminently conspicuous, in the portion of the production of Nature. How these changes are produced, is a question solved with difficulty. Mr. Murray appears disposed to think, they depend upon the accumulation of oxygen in the plant, which is disregarded thro' the influence of light, >

In animals nearly the same effects are produced; Man is indebted to light for his colour & the most numerous of his pleasures; and the variety & brilliancy of his tint with in animals, particularly of the feathered tribes of tropical regions, fully establishes the truth of the proposition. Light has been observed to have considerable influence on the mass of blood, by Mr. Junt. of Richmond, who published his inaugural dissertation, some years ago, in this city. This gentleman exposed human blood to the influence of light, taking every precaution to exclude atmospheric air, & avoid pallors. In these experiments, he uniformly found a change of colour to be produced, that resembled the warm

-tion induced by the action of atmospheric air in the lungs. The colour was not so intense as that of arterial blood, or that of blood submitted to the coagulative action of air and light, but sufficient to ascertain that some change was effected, & this experiment was so varied, as to prove the result, to be the action of light alone.

But I do attempt collecting all the facts that might be adduced, in favour of the chemical agency of light, the patience of my reader would be worn out, & this would be extended further than the limits of an essay. (We have not only) the facts already mentioned, but the opinion of many celebrated philosophers, whose judgments have been matured by reflection, deliberation & experience. "We can no longer," says Chaplat consider light as a merely physical substance, the chemist perceives its influence in most of his experiments, & finds it necessary to attend to its action which modifies his results. & its effects are no less evident in the various phenomena of nature than in the operations performed in our laboratories". (Mr. Murray, when writing) "and among the most valuable productions of (Bosch) of mind, and whose observation are entitled to our attention, shows, that next to oxygen, light is perhaps the most extensive in its influence of any chemical agent. These two principles may even be regarded as antagonists, the combination of

oxygen being generally attended within by the separation of light in a sensible form or its transition into a state of mere combination; while oxygen is scarcely ever dissipated without the interference of fire or combined light.

Under our second head we propose making some inquiries into the combinations of light. By analysis or synthesis, we usually ascertain the existence of a principle in a compound body. That light is capable of entering into combinations, may be proved by either. By analytical experiment, we ascertain the presence of light in oxygen gas. If an ignited piece of charcoal be placed in a vessel of oxygen gas, the gas will disappear, with the evolution of its heat & light, and carbonic acid gas will be formed. Mr. Davy proved by the following experiment, that light is a principle of oxygen gas, & establishes in the most unequivocal manner, that light does not exist in Carbonic acid gas. "A small gun cock armed with an excellent flint, was snapped in a vessel filled with oxygen gas. The particles of flint separated by collision were the most brilliant that can be imagined; and these particles, surrounded by a magnifying lens, found to be converted into black oxide of iron. The same experiment was made in a vessel filled with Carbonic acid gas, the iron was found but no light was liberated". We have already stated, that the existence of light in oxygen gas may be proved in a sensible manner. It appears to be pro-

perfectly understood in chemical combination, that a body
which is capable of one combination, is or may be com-
bined, with a variety of other substances. Mr Murray
when speaking of light, observed, "if the opinion be maintain-
ed, that it is a component principle of combustible bodies, it
will be extracted in dephlogation from the inflammable
body; whilst if it be a constituent principle of oxygen gas
it may still be derived from this source, for when oxy-
gen is combined with Hydrogen, no light is extracted and therefore
if oxygen gas, it contains light, then light must be an essen-
tial part of it as it exists in the state of potassa". May
we not infer from analogy that it enters into many other
chemical combinations. The combinations of the same acids
or salts, in different proportions, will produce compounds
differing in their physical or chemical properties, from the
original. If this we have an example in the combination
of oxygen & nitrogen - In these combinations the peculiar
properties of the compound depend on the presence of
each of the constituents - Abstract one & you destroy the
compound - proving that each constituent, confers a specific
or determinate property. Most of the writers on chemical
subjects appear disposed to bestow greater power on one sub-
stance than another, in chemical combination - thus, oxygen
is considered the nature the basis of a combination. To

proven that this is incorrect, it is only necessary to propose
two questions. Does oxygen, in the purest form we can obtain it,
possess in itself, any property of an acid? An acid properties
compound, in all its combinations?

I conceive that the existence of light in oxygen gas, is suffi-
ciently clear. What then becomes of the principle, when oxy-
gen & hydrogen are combined to form water? In this process
the evolved heat is intense, and the light should be visible,
if in the same ratio, if it was set free by the combination,
on the contrary, the light produced by the combination is
by no means in the proportion that may be evolved by
other means. If light exists in combination with oxygen
- it is not set free by the combination of this with hydrogen,
- the conclusion must be that it makes a part of the product.

I cannot conceive of any substance attached to a conclu-
sion of this nature. Instances almost innumerable may be ad-
duced analogous to this, of one body entering into combina-
tion with others & producing substances totally distinct & in
some instances directly ^{opposite in their properties,} Thus oxygen & nitrogen in different
proportions form atmospheric air nitrous oxide, nitrous acid
& nitrous acid - Oxygen has been proved to be the principle
of acidification & alkaliescence - Hydrogen, the lightest of
bodies in its gaseous state, is found to exist in the hard-
est, & most rationally supposed to form a constituent principle
of the metals, substances of the greatest specific gravity.

That class of bodies termed the phosphori possess the property of combining with light when exposed to it, & of emitting it again when carried into a dark place. The emission of the light appears to be very much accelerated, by the application of heat. It appears from the experiments of Messrs Dufay & Wilson, as related by Dr. Sir Murray, that the light emitted from phosphorescent bodies is not influenced by a single prismatic ray.

If a piece, for instance, which in the dark gives a white light, have a red light thrown upon it, or be exposed to any other ray, it still continues to give out an amorphous white light. These facts, says Murray, "are conformable to the conclusion, that the light which the phosphorescent bodies emit, is that which they had previously absorbed, and have led some to infer that they then by emitting, their own light, & that exposure to light is only necessary to excite this & cause it to be thrown off. It is not improbable, however, that the different varieties of light are convertible into each other, and on this supposition the fact may be accounted for, in conformity with the common theory of phosphorescence".

Can it be possible that light is purely physical in its nature? Reason & true philosophy answer in the negative. I conceive that the production of colour, odour, pungency of taste, &c. are as much the result of a chemical action, as the production of co-

lower in dyeing, the formation of ammonia, or
nitric acid! Mr. Lavoisier observes, that experiments
upon vegetation give reason to believe, that light com-
bines with certain parts of vegetables. Mr. Davy has as-
certained by experiment that the colour of vegetables, depends
on light, & when this is excluded they become white, not-
withstanding they were naturally of a deep colour? And
that flowers naturally white, when exposed to an intense
light become bright coloured. Some plants, possessing de-
lirious properties become perfectly harmless by being
kept in a dark place. Mr. Humezoy observes, that not
only the colour of vegetables depends on light, but so do
they are indebted for their smell taste, combustibility, &
resinous principle. Hence aromatic substances, resin-
scented oils, and those colouring matters, of so much value
for their livery & dye, are peculiar to southern climates,
where the light is more constant and intense. D. Barton
observed in his lectures, that plants exposed to the action
of the heat rays, yield most sugar.

In the combustion of different substances, we frequently
by must observe, that the colour of the flame is ^{1. say} not the same
- May not the variety of shade, be owing to the in-
flammation, or product of the inflammation, combining
with some of the rays of light, & to the evolution of
the others? Or do the rays of light carry off a portion
of the combustible & thus leave it of any colour depend-
ing on the combustible? The former is the most probable.

In this experiment it was inflammable matter in the
can, & the action of the charcoal in the thin tube gave
to his error.

Murray, Chemistry, Ed. 2. Vol. 1. p. 18

The arguments brought forward, I conceive to establish the plausibility of the combinations of light, sufficiently clearly. It is a more difficult task to explain the nature of the combinations - to ascertain the particular rays of light, & the parts with which they combine. I make no doubt that some of the effects of light are explicable on ~~the~~ its deoxidizing property, yet I think it equally probable that the rays are in some instances combined with some of the constituent principles of the vegetable.

Under my third Head I propose to make some inquiries into the relation of light to other chemical agents.

Heat and light were at one time thought to be one and the same - or rather one was thought to be the effect of the other; Hence Mr. Lavoisier declares, "we are unable to determine whether light be a modification of Caloric, or, on the contrary, caloric be a modification of Light."

The ingenious Count Rumford made some experiments to prove that the chemical powers of light were not independent of ~~the~~ the heat that was excited. His experiments appeared to warrant a conclusion of this kind; but unfortunately for this theory, the result was proved, by Mr. Fulkerson, & Berthollet who repeated these experiments, not to be caused by the action of heat, but by some extraneous matter.

because it is unconfined - or when we cannot obtain the
parts we wish to investigate in sufficient quantity or in a ben-
eform. - we shall be justifiable in judging of the nature of
it, from its effects & the analogous effects of others.

Amidst the number of agents with which the science of
Chemistry is enriched, there is none, which I conceive to
be so nearly allied to light, as Galvanism. This must
be necessarily hypothetical, yet when we reflect on the ana-
logy which subsists between them in their effects on bodies,
submitters to their action, and when we observe the great
variety of compounds produced from a few principles, our as-
tonishment wears off, & we begin to look on it with
an eye of greater complacency. The agency of galvanism
appears to consist in violent attractions and repulsion, per-
taining the property of conveying the principles of the de-
composed substance to a distance, & even through substances
which have a strong affinity for them. This we do not ob-
serve in the agency of light - May, not this be owing
to our not being acquainted with an apparatus, which
could concentrate the rays of light sufficiently, & exclude
those which do not possess a chemical power? By far
the most important agency of galvanism is that which
subverts combination & gives rise to chemical decomposi-
tion - possesses a power greater than that of any

agent hitherto known & which may be increased to
any extent by enlarging the apparatus. The great ana-
lytic Light & galvanism, I conceive to exist in the pow-
er of one, in occasioning decomposition, & abstracting
oxygen, and that which is termed the positive effect of the
other. We have mentioned a number of substances, which are
powerfully acted on by light & decomposed by the abstraction
of their oxygen. And we have seen that light, is in some
instances capable of separating the acid from a base, which
has a powerful affinity for it. These are not the only ar-
guments, in favor of the relation of the two agents. In a
preceding part of this essay we have proved that light
enters into combination to form nitric acid. Now the
effects of galvanism may be produced by this, & other sub-
stances, into the composition of which, light enters. "If a de-
cided be formed of water, nitric, & diluted nitric acid, the
production of galvanism is evident, though not considerable."
Mr. Davy observed, that a piece of charcoal, in contact at one
ext. its surfaces with water, at another with nitric acid,
shows signs of galvanism.[†] May not this be owing to the ex-
trication of light from its combinations, producing the effect
of galvanism. When we reflect that so little is known of the
articles of these agents & so much is so learned, that the only
method we have of acquiring an accurate knowledge, rather

is by attentively observing the phenomena produced by them
on different bodies, & that each possesses the property of decom-
posing salts, acids, &c. by their specific power. May we not
infer that they are intimately connected, one with the o-
ther. Whatever may be the relation, which shall be found to
exist between them, certain it is, that their effects are in many
instances very similar - the difference, I conceive to be explain-
able on the grounds of the great expansion of the chemical
particles of light, & the condensation of the galvanic influ-
ence - I have thus thrown a few unconnected thoughts together
on a subject, which has not made such rapid strides towards
completion, as others have, that come equally under the consideration
of the natural philosopher & chemist. To Mr. Murray's system of
chemistry I have been much indebted. I have taken the liberty
of transcribing many sentences from authors, which could not be
expressed in other words, without doing an injury to the intention.
A number of circumstances might be urged to palliate the
want of originality of the composition - Lack, bad health, & the anxiety in-
fluently attendant on a candidate for medical honors, whose
entire success in life depends on the result - Was this factu-
al production to be stripped of its borrowed feathers, it would
be naked indeed. Let me solicit your indulgence for the
errors contained in this, the first production of the -

Author.

Medical Effects

of

Sighs and Suffering.

Thos. Sullis Jr.

1809
